#### Abstract

Efficient proof methods for proving properties specified by means of normal modal logics are highly desirable, as such logical systems have been widely used in computer science to represent complex situations. Resolution-based methods are often designed to deal with formulae in a normal form and the efficiency of the method (also) relies on how efficient (in the sense of producing fewer and/or shorter clauses) the translation procedure is. We present a normal form for normal modal logics and show how the use of simplification, for specific normal logics, together with anti-prenexing and prenexing techniques help us to produce better sets of clauses.

## 1 Introduction

Beliefs, knowledge, intentions, desires, and obligations of agents as well as the behaviour of these (and possibly other) aspects over time are often used to describe complex situations in computer science. This is the case, for instance, in the specification of distributed [3] and multi-agent systems [9]. Normal modal logics are often chosen to model and reason about these situations. Given a logical specification, an automated tool such as, for instance, a theorem prover, can then be used for verifying properties of the system. However, in order to model the different aspects of a complex, particular situation, it may be necessary to combine different logical languages. When the combination is given by the fusion of logical systems, that is, when the components are independently axiomatisable, proofs can be obtained by combining the provers for each language. Combining those provers may require special care such that all relevant information is correctly handled and exchanged between the different tools. Also, this may require the use of tools which are based on different implementations (e.g. different input languages) or, worse, on different approaches (e.g. partially based on translation to first-order language $\times$ partially based on the modal language, resolution $\times$ tableau, etc), making this task harder.

We are currently investigating a uniform approach which deals with theorem proving for a variety of propositional normal modal logics, that is, logics in which
the schema $\square(\varphi \Rightarrow \psi) \Rightarrow(\square \varphi \Rightarrow \square \psi)$ (the axiom $\mathbf{K})$, where $\square$ is the modality for necessity and $\varphi$ and $\psi$ are well-formed formulae, is valid. We are interested in multi-modal normal logics based on the following axioms

$$
\begin{aligned}
& \mathbf{K}: \square(\varphi \Rightarrow \psi) \Rightarrow(\square \varphi \Rightarrow \square \psi) \\
& \mathbf{T}: \square \varphi \Rightarrow \varphi \\
& \mathbf{D}: \square \varphi \Rightarrow \diamond \varphi \\
& \mathbf{4}: \square \varphi \Rightarrow \square \square \varphi \\
& \mathbf{5}: \diamond \varphi \Rightarrow \square \diamond \varphi \\
& \mathbf{B}: \diamond \square \varphi \Rightarrow \varphi
\end{aligned}
$$

where $\diamond$ is the modality for possibility. We formally introduce the weakest of these logics, $\mathrm{K}_{(n)}$, in Section 2. The proof method for each logic is resolutionbased and our approach is clausal: in order to prove that a formula, $\varphi$, is valid, we first transform its negation, $\neg \varphi$, into a clausal normal form. Here we do not focus on the proof method, but on the properties that a normal form for these logics should have in order to achieve efficiency. We discuss briefly some aspects that should be considered when designing a normal form for a family of logics.

Firstly, in the propositional case there is only one resolution rule to apply to the set of clauses, whilst we often need several rules for dealing with modal logics. This happens because the semantics of modal logics are relative to a set of worlds, so we often need to perform reasoning tasks which are not local (to the actual world). Also, if we consider multi-agents contexts, the resolution rules must consider the different contexts (relative to each agent) in which the reasoning applies. Separating these contexts may facilitate the reasoning task. Thus, it should be taken into consideration when designing a normal form for these logics.

Also, we should think of strategies that could be used to reduce the proof search. Our work is based on that of [1], but the normal form differs slightly (where $l_{i}$ are literals, i.e., propositions or their negations): clauses are separated into literal clauses (disjunctions of literals), positive modal clauses (an implication as $l_{1} \Rightarrow \square l_{2}$ ), and negative modal clauses (an implication as $l_{1} \Rightarrow \neg \square l_{2}$ ). This further separation potentially allows a better design of strategies to guide the search for a proof when applying the resolution method. For instance, complete strategies for (purely) propositional logic could be used when the parents are literal clauses. The set of support strategy could also be used when the parents are modal clauses, taking, for instance, the positive modal clauses in the usable set and the negative modal clauses in the set of support (or vice-versa).

The new normal form is given in Section 3. Transformation into clausal form is carried out by performing classical style rewriting, simplification, and renaming [8], a technique which may avoid combinatorial explosion on the size of the formula by replacing complex subformulae by new symbols, whose meaning are linked to the formula that they are replacing.

Efficient translation is crucial for practical use of the resolution method. By efficient we mean that the translation method produces fewer or shorter clauses. In first-order logic, it has been shown [2] that the transformation of a given
problem into anti-prenex normal form (i.e. when quantifiers are moved inwards a formula) results in a better set of clauses. However, to the best of our knowledge, there has not been a similar investigation for modal logics. We present an algorithm for anti-prenexing in Section 4. Experimentally, anti-prenexing together with simplification, given in Section 5, followed by transformation into the normal form performs better than both the transformation preceded by antiprenexing and transformation alone.

We introduce the prenex normal form in Section 6 and show how this can also be used to reduce the nesting of modal operators after anti-prenexing. Simplification for specific logics is used in both steps, anti-prenexing and prenexing. Preliminary results show that the set of clauses is usually smaller than that obtained by translation into the normal form alone.

Experimental results are given in Section 7. We provide concluding remarks in Section 8.

## 2 The Basic Normal Logic

The basic normal modal logic that we present here is known as $\mathrm{K}_{(n)}$. This is the weakest of the normal modal systems, where only the distribution axiom (the axiom $\mathbf{K}$ ) holds. There is no restriction on the accessibility relation over worlds. As the subscript in the name of the logic indicates, we consider the multi-agent version, given by the fusion of several copies of $\mathrm{K}_{(1)}$, one for each agent.

### 2.1 Syntax

Formulae are constructed from a denumerable set of propositional symbols, $\mathcal{P}=$ $\left\{p, q, p^{\prime}, q^{\prime}, p_{1}, q_{1}, \ldots\right\}$. The finite set of agents is defined as $\mathcal{A}=\{1, \ldots, n\}$. In addition to the standard propositional connectives $(\neg, \vee, \wedge, \Rightarrow)$, we introduce a set of unary modal operators $1, \ldots, \square$, where $i \varphi$ is read as "agent $i$ considers $\varphi$ necessary". When $n=1$, we may omit the index, that is, $\square \varphi=\square \varphi$. We do not define the operator $\diamond$ : the fact that an "agent $i$ considers $\varphi$ possible" is expressed by $\neg \boxed{i} \neg \varphi$. The language of $\mathrm{K}_{(n)}$ is defined as follows:
Definition 1. The set of well-formed formulae, $\mathrm{WFF}_{\mathrm{K}_{(n)}}$ :

- the propositional symbols are in $\mathrm{WFF}_{\mathrm{K}_{(n)}}$;
- true and false are in $\mathrm{WFF}_{\mathrm{K}_{(n)}}$;
- if $\varphi$ and $\psi$ are in $\mathrm{WFF}_{\mathrm{K}_{(n)}}$, then so are $\neg \varphi,(\varphi \wedge \psi),(\varphi \vee \psi),(\varphi \Rightarrow \psi)$, and $\lceil\varphi(\forall i \in \mathcal{A})$.

The following definitions will also be used later.
Definition 2. A literal is either a proposition or its negation.
Definition 3. A modal literal is either $i l$ or $\neg l$, where $l$ is a literal and $i$ is in the set of agents, $\mathcal{A}=\{1, \ldots, n\}$.

Definition 4. A formula $\chi$ is disjunctive if, and only if, is of the form $(\varphi \Rightarrow$ $\psi),(\varphi \vee \psi)$ or $\neg(\varphi \wedge \psi)$. Otherwise, $\chi$ is said to be conjunctive.

Polarity of a formula is defined as usual: if a formula is inside the scope of an even (including zero) number of negation symbols, the formula is said to be of positive polarity; otherwise, it is of negative polarity.

### 2.2 Semantics

Semantics of $\mathrm{K}_{(n)}$ is given, as usual, in terms of a Kripke structure.
Definition 5. A Kripke structure $M$ for nagents over $\mathcal{P}$ is a tuple $M=$ $\left\langle\mathcal{S}, \pi, \mathcal{R}_{1}, \ldots, \mathcal{R}_{n}\right\rangle$, where $\mathcal{S}$ is a set of possible worlds (or states) with a distinguished world $s_{0}$; the function $\pi(s): \mathcal{P} \rightarrow\{$ true, false $\}$, $s \in \mathcal{S}$, is an interpretation that associates with each state in $\mathcal{S}$ a truth assignment to propositions; and $\mathcal{R}_{i}$ is a binary relation on $\mathcal{S}$.

The binary relation $\mathcal{R}_{i}$ is intended to capture the possibility relation according to agent $i$. So, a pair $(s, t)$ is in $\mathcal{R}_{i}$ if agent $i$ considers world $t$ possible, given her information in world $s$. In $\mathrm{K}_{(n)}$, the relations are any subsets of $S \times S$.

Truth is defined in terms of the relation $\models$. We write $(M, s) \models \varphi$ to express that $\varphi$ is true at world $s$ in the Kripke structure $M$.

Definition 6. Truth of a formula is given as follows:
$-(M, s) \models$ true

- $(M, s) \not \models$ false
$-(M, s) \models p$ if, and only if, $\pi(s)(p)=$ true, where $p \in \mathcal{P}$
$-(M, s) \models \neg \varphi$ if, and only if, $(M, s) \not \models \varphi$
$-(M, s) \models(\varphi \wedge \psi)$ if, and only if, $(M, s) \models \varphi$ and $(M, s) \models \psi$
$-(M, s) \models(\varphi \vee \psi)$ if, and only if, $(M, s) \models \varphi$ or $(M, s) \models \psi$
$-(M, s) \models(\varphi \Rightarrow \psi)$ if, and only if, $(M, s) \models \neg \varphi$ or $(M, s) \models \psi$
$-(M, s) \models i \varphi$ if, and only if, for all $t$, such that $(s, t) \in \mathcal{R}_{i},(M, t) \models \varphi$.
Formulae are interpreted with respect to the distinguished world $s_{0}$. Intuitively, $s_{0}$ is the world from which we start reasoning. Let $M=\left\langle\mathcal{S}, \pi, \mathcal{R}_{1}, \ldots, \mathcal{R}_{n}\right\rangle$ be a Kripke structure. Thus, a formula $\varphi$ is said to be satisfiable in $M$ if $\left(M, s_{0}\right) \models \varphi$; it is said to be satisfiable if there is a model $M$ such that $\left(M, s_{0}\right) \models \varphi$; and it is said to be valid if for all models $M$ then $\left(M, s_{0}\right) \models \varphi$.

## 3 A Normal Form for $\mathrm{K}_{(n)}$

Formulae in the language of $\mathrm{K}_{(n)}$ can be transformed into a normal form called Separated Normal Form for Normal Logics $\left(\mathrm{SNF}_{K}\right)$. We introduce a nullary connective start, in order to represent the world from which we start reasoning. Formally, we have that $(M, s) \models$ start if, and only if, $s=s_{0}$. A formula in $\mathrm{SNF}_{K}$
is represented by a conjunction of clauses, which are true at all states, that is, they have the general form

$$
\square^{*} \bigwedge_{i} A_{i}
$$

where $A_{i}$ is a clause and $\square$ *, the universal operator is defined as:

$$
(M, s) \models \square^{*} \varphi \text { if, and only if, }(M, s) \models \varphi \text { and for all } s^{\prime} \text { such that }\left(s, s^{\prime}\right) \in
$$ $\mathcal{R}_{i}$, for some $i \in \mathcal{A},\left(M, s^{\prime}\right) \models$ $\qquad$ ${ }^{*} \varphi$.

Observe that $\varphi$ holds at the actual world $s$ and at every world reachable from $s$, where reachability is defined in the usual way. That is, let $M$ be a model and $u$ and $u^{\prime}$ be worlds in $M$. Then $u^{\prime}$ is reachable from $u$ if, and only if, either (i) $\left(u, u^{\prime}\right) \in \mathcal{R}_{i}$ for some agent $i \in \mathcal{A}$; or (ii) there is a world $u^{\prime \prime}$ in $M$ such that $u^{\prime \prime}$ is reachable from $u$ and $u^{\prime}$ is reachable from $u^{\prime \prime}$. The universal operator, which surrounds all clauses, ensures that the translation of a formula is true at all worlds. Clauses are in one of the following forms:

- Initial clause

$$
\text { start } \Rightarrow \bigvee_{b=1}^{r} l_{b}
$$

- Literal clause

$$
\text { true } \Rightarrow \bigvee_{b=1}^{r} l_{b}
$$i-clause

$$
l \Rightarrow m_{i}
$$

where $l$ and any $l_{b}$ are literals and $m_{i}$ is a modal literal containing a $i$ or a $\neg i$ operator. In general, that is, when we do not need to specify a particular agent, we often write modal clause to refer to a $i$-clause.

### 3.1 Transformation into Normal Form

The translation to $\mathrm{SNF}_{K}$ uses the renaming technique [8], where complex subformulae are replaced by new propositional symbols and the truth of these new symbols is linked to the formulae that they replaced in all states. The translation into $\mathrm{SNF}_{K}$ of a given formula $\varphi$ of $\mathrm{K}_{(n)}$ is given by the following transformation functions, $\tau_{0}$ and $\tau_{1}$, where $x$ is a new propositional symbol:

$$
\tau_{0}(\varphi)=\square^{*}(\text { start } \Rightarrow x) \wedge \tau_{1}\left(\square^{*}(x \Rightarrow \varphi)\right)
$$

The function $\tau_{0}$ is used to anchor the meaning of $\varphi$ to the initial world, where the formula is evaluated. The function $\tau_{1}$ proceeds with the translation, removing
classical operators, by means of classical rewriting operations, and replacing complex formulae which appear in the scope of the i operator, by means of renaming. The next rewriting rules deal with classical operators (where $A$ and $B$ are formulae, and $x$ is the propositional symbol introduced by the function $\tau_{0}$ ):

$$
\begin{aligned}
\tau_{1}\left(\square^{*}(x \Rightarrow \neg \neg A)\right) & =\tau_{1}\left(\square^{*}(x \Rightarrow A)\right) \\
\tau_{1}\left(\square^{*}(x \Rightarrow(A \wedge B))\right) & =\tau_{1}\left(\square^{*}(x \Rightarrow A)\right) \wedge \tau_{1}\left(\square^{*}(x \Rightarrow B)\right) \\
\tau_{1}\left(\square^{*}(x \Rightarrow(A \Rightarrow B))\right) & =\tau_{1}\left(\square^{*}(x \Rightarrow \neg A \vee B)\right) \\
\tau_{1}\left(\square^{*}(x \Rightarrow \neg(A \wedge B))\right) & =\tau_{1}\left(\square^{*}(x \Rightarrow \neg A \vee \neg B)\right) \\
\tau_{1}\left(\square^{*}(x \Rightarrow \neg(A \Rightarrow B))\right) & =\tau_{1}\left(\square^{*}(x \Rightarrow A)\right) \wedge \tau_{1}\left(\square^{*}(x \Rightarrow \neg B)\right) \\
\tau_{1}\left(\square^{*}(x \Rightarrow \neg(A \vee B))\right) & =\tau_{1}\left(\square^{*}(x \Rightarrow \neg A)\right) \wedge \tau_{1}\left(\square^{*}(x \Rightarrow \neg B)\right)
\end{aligned}
$$

We rename complex subformulae enclosed in a modal operator as follows, where $y$ is a new proposition and $A$ is not a literal.

$$
\begin{gathered}
\tau_{1}\left(\square^{*}(x \Rightarrow i A)\right)=\tau_{1}\left(\square^{*}(x \Rightarrow \square y)\right) \wedge \tau_{1}\left(\square^{*}(y \Rightarrow A)\right) \\
\tau_{1}\left(\square^{*}(x \Rightarrow \neg i A)\right)=\tau_{1}\left(\square^{*}(x \Rightarrow \neg \square \neg y)\right) \wedge \tau_{1}\left(\square^{*}(y \Rightarrow \neg A)\right)
\end{gathered}
$$

Next we use renaming on formulae whose right-hand side has disjunction as its main operator but may not be in the correct form (where $y$ is a new proposition, $D$ is a disjunction of formulae, $A$ is not a literal or an implication, and $D^{\prime}$ and $D^{\prime \prime}$ are formulae):

$$
\begin{aligned}
\tau_{1}\left(\square^{*}\left(x \Rightarrow D \vee\left(D^{\prime} \Rightarrow D^{\prime \prime}\right)\right)\right) & =\tau_{1}\left(\square^{*}\left(x \Rightarrow D \vee \neg D^{\prime} \vee D^{\prime \prime}\right)\right) \\
\tau_{1}\left(\square^{*}(x \Rightarrow D \vee A)\right) & =\tau_{1}\left(\square^{*}(x \Rightarrow D \vee y)\right) \wedge \tau_{1}\left(\square^{*}(y \Rightarrow A)\right)
\end{aligned}
$$

Finally, we rewrite formulae whose right-hand side is a disjunction of literals into clause form, that is, as an implication. Modal clauses whose right-hand side is a modal literal are already in the normal form, so no further transformation is required. Note that each modal clause contains only one modal literal. So, the different contexts belonging to different agents are already separated at the end of the translation and we do not require further renaming as in [1].

$$
\tau_{1}\left(\square^{*}(x \Rightarrow D)\right)= \begin{cases}\square^{*}(\text { true } \Rightarrow \neg x \vee D) & \text { if } D \text { is a disjunction of literals } \\ \square^{*}(x \Rightarrow D) & \text { if } D \text { is a modal literal }\end{cases}
$$

As an example, the translation of $1(a \Rightarrow b) \Rightarrow(\square a \Rightarrow \square b)$ is given by:

$$
\begin{aligned}
\tau_{0}(\square(a \Rightarrow b) \Rightarrow(\square a \Rightarrow \square b))= & \square^{*}\left(\text { start } \Rightarrow t_{1}\right) \wedge \\
& \tau_{1}\left(\square^{*}\left(t_{1} \Rightarrow \square(a \Rightarrow b) \Rightarrow(\square a \Rightarrow \square b)\right)\right)
\end{aligned}
$$

where

$$
\tau_{1}\left(\square^{*}\left(t_{1} \Rightarrow \square(a \Rightarrow b) \Rightarrow(\square a \Rightarrow \square b)\right)\right)=
$$

$$
\begin{aligned}
= & \tau_{1}\left(\square^{*}\left(t_{1} \Rightarrow \neg(\square(a \Rightarrow b)) \vee(\square a \Rightarrow \square b)\right)\right) \\
= & \tau_{1}\left(\square^{*}\left(t_{1} \Rightarrow t_{2} \vee \neg \square a \vee \square b\right)\right) \wedge \tau_{1}\left(\square^{*}\left(t_{2} \Rightarrow \neg(\square(a \Rightarrow b))\right)\right) \\
= & \tau_{1}\left(\square^{*}\left(t_{1} \Rightarrow t_{2} \vee t_{3} \vee t_{4}\right)\right) \wedge \tau_{1}\left(\square^{*}\left(t_{2} \Rightarrow \neg \square \neg t_{5}\right)\right) \wedge \tau_{1}\left(\square^{*}\left(t_{3} \Rightarrow \neg \square a\right)\right) \wedge \\
& \tau_{1}\left(\square^{*}\left(t_{4} \Rightarrow \square b\right)\right) \wedge \tau_{1}\left(\square^{*}\left(t_{5} \Rightarrow \neg(a \Rightarrow b)\right)\right) \\
= & \square^{*}\left(\text { true } \Rightarrow \neg t_{1} \vee t_{2} \vee t_{3} \vee t_{4}\right) \wedge \square^{*}\left(t_{2} \Rightarrow \neg \square \neg t_{5}\right) \wedge \square^{*}\left(t_{3} \Rightarrow \neg \square a\right) \wedge \\
& \left.\square^{*}\left(t_{4} \Rightarrow \square b\right) \wedge \tau_{1}\left(\square^{*}\left(t_{5} \Rightarrow a\right)\right) \wedge \tau_{1}\left(\square \square^{*}\left(t_{5} \Rightarrow \neg b\right)\right)\right) \\
= & \square^{*}\left(\text { true } \Rightarrow \neg t_{1} \vee t_{2} \vee t_{3} \vee t_{4}\right) \wedge \square^{*}\left(t_{2} \Rightarrow \neg \square \neg t_{5}\right) \wedge \square^{*}\left(t_{3} \Rightarrow \neg \square a\right) \wedge \\
& \square^{*}\left(t_{4} \Rightarrow \square b\right) \wedge \square^{*}\left(\text { true } \Rightarrow \neg t_{5} \vee a\right) \wedge \square^{*}\left(\text { true } \Rightarrow \neg t_{5} \vee \neg b\right)
\end{aligned}
$$

The translation procedure results in 7 clauses: one initial, three literal, and three modal clauses. Note also that the new propositional symbols $t_{i},(1 \leq i \leq 5)$, were introduced during renaming of complex formula: either a disjunct which is not a literal or a complex formula inside the scope of a modal operator.

### 3.2 Correctness of Translation

In order to prove that the translation into normal form is satisfiability preserving, we need to prove the following lemmas. Firstly, we show that if the translated formula is satisfiable in a model, then the original formula is also satisfiable.

Lemma 1. Let $\varphi$ be a formula in $\mathrm{K}_{(n)}$, and $M$ be a model. If $M \models \tau_{1}\left(\square^{*}(x \Rightarrow\right.$ $\varphi)$ ), then $M \models \square^{*}(x \Rightarrow \varphi)$, where $x$ is a propositional symbol.

Proof. By induction on the structure of $\varphi$. In the following $s$ is a world in $M$. For the base cases, $\varphi$ is a disjunction of literals or a modal literal. The latter is obvious. We show that if $D$ is a disjunction of literals and $(M, s) \models \tau_{1}\left(\square^{*}(x \Rightarrow\right.$ $D)$ ), then $(M, s) \models \square^{*}(x \Rightarrow D)$. If $(M, s) \models \tau_{1}\left(\square^{*}(x \Rightarrow D)\right)$, then, by the transformation givent by $\tau_{1},(M, s) \models \square^{*}($ true $\Rightarrow \neg x \vee D)$. By semantics of the universal operator, for any world $t$ reachable from $s$, we have $(M, t) \models($ true $\Rightarrow$ $\neg x \vee D)$. By propositional reasoning $(M, t) \models(\neg$ true $\vee \neg x \vee D)$, which simplifies to $(M, t) \models(\neg x \vee D)$, as $\neg$ true cannot be satisfied. Again, by propositional reasoning, $(M, t) \models(x \Rightarrow D)$. By semantics of $\square^{*}$, as $t$ is any world reachable from $s$, we have that $(M, s) \models \square^{*}(x \Rightarrow D)$.

We only prove the case where $\varphi$ is of the form $\square A$, where $A$ is not a literal, that is, if $(M, s) \models \tau_{1}\left(\square^{*}(x \Rightarrow i A)\right.$, we show that $(M, s) \models \square^{*}(x \Rightarrow i A)$. The cases for other operators are similar. If $(M, s) \models \tau_{1}\left(\square^{*}(x \Rightarrow i A)\right.$, we first show that $(M, s) \models \tau_{1}\left(\square^{*}(x \Rightarrow \square y)\right) \wedge \tau_{1}\left(\square^{*}(y \Rightarrow A)\right)$. If $(M, s) \models$ $\tau_{1}\left(\square^{*}(x \Rightarrow \square y)\right.$ ), then (i) $(M, s) \models \square^{*}(x \Rightarrow \square y)$ (as this is a base case). If $(M, s) \models \tau_{1}\left(\square^{*}(y \Rightarrow A)\right.$ ), by induction hypothesis, (ii) $(M, s) \models \square^{*}(y \Rightarrow A)$. Let $t$ be a world in $M$, such that $t=s$ or $t$ is reachable from $s$. From (i), (ii), the semantics of $\square^{*}$, and propositional reasoning, we have $(M, t) \models((x \Rightarrow$ $(y) \wedge(y \Rightarrow A))$. Also, if $\left(t, t^{\prime}\right) \in \mathcal{R}_{i}$, for some $t^{\prime}$ in $M$, by semantics of $i$, we have that if $(M, t) \models x$, then $\left(M, t^{\prime}\right) \models y$. As $t^{\prime}$ is also reachable from $s$, from (ii), by propositional reasoning, we have ( $M, t^{\prime}$ ) $\vDash A$. Thus, by semantics of necessitation, $(M, t) \models(x \Rightarrow \square A)$, for all $t$ reachable from $s$. By semantics of $\square^{*}$, we have $(M, s) \models \square^{*}(x \Rightarrow i A)$.

Lemma 2. Let $\varphi$ be a formula in $\mathrm{K}_{(n)}$, $M$ be a model. If $M \models \tau_{0}(\varphi)$, then $M \models \varphi$.

Proof. Let $s$ be a world in $M$. If $(M, s) \models \tau_{0}(\varphi)$, we first show that $(M, s) \models$ $\square^{*}($ start $\Rightarrow x) \wedge \tau_{1}\left(\square^{*}(x \Rightarrow \varphi)\right)$. By semantics of $\square^{*},(M, s) \models($ start $\Rightarrow x)$. Suppose that $(M, s) \models$ start (otherwise we are done). Then by semantics of implication, (i) $(M, s) \models x$. By Lemma 1, if $(M, s) \models \tau_{1}\left(\square^{*}(x \Rightarrow \varphi)\right)$, then $(M, s) \models \square^{*}(x \Rightarrow \varphi)$. By semantics of $\square^{*}$, we have (ii) $(M, s) \models(x \Rightarrow \varphi)$. From (i) and (ii), by propositional reasoning, $(M, s) \models \varphi$.

Next we show that if a formula is satisfiable, then its translation into normal form also is satisfiable. The next lemma shows that the transformation function $\tau_{1}$ preserves satisfiability.

Lemma 3. Let $\square^{*}(x \Rightarrow \varphi)$, where $x$ is a propositional symbol. Let $M=$ $\left\langle\mathcal{S}, \mathcal{R}_{1}, \ldots, \mathcal{R}_{n}, \pi\right\rangle$ be a model. If $M \models \square^{*}(x \Rightarrow \varphi)$, then there is a model $M^{\prime}$ such that $M^{\prime} \models \tau_{1}\left(\square^{*}(x \Rightarrow \varphi)\right)$.

Proof. By induction on the structure of $\varphi$. Suppose that $M \models \square^{*}(x \Rightarrow \varphi)$, we show how to construct a model $M^{\prime}$ such that $M^{\prime} \models \tau_{1}\left(\square^{*}(x \Rightarrow \varphi)\right)$. The application of $\tau_{1}$ consists of two main operations: rewriting and renaming. We examine both operations. For the base cases, that is, if $\varphi$ is a disjunction of literals or a modal literal, we do not introduce new propositional symbols and we only need propositional reasoning to show that taking $M^{\prime}=M$, we have $M^{\prime} \models \tau_{1}\left(\square^{*}(x \Rightarrow \varphi)\right)$.

Assume that $\varphi$ is of the form $A \wedge B$. Then $\tau_{1}\left(\square^{*}(x \Rightarrow(A \wedge B))\right)$ is given by $\tau_{1}\left(\square^{*}(x \Rightarrow A)\right) \wedge \tau_{1}\left(\square^{*}(x \Rightarrow B)\right)$. Clearly, if $M \models\left(\square^{*}(x \Rightarrow(A \wedge B))\right)$, then $M \models\left(\square^{*}(x \Rightarrow A)\right)$ and $M \models\left(\square^{*}(x \Rightarrow B)\right)$. By induction hypothesis, taking $M^{\prime}$ exactly as $M$, we obtain a model which satisfies the translation, that is, $M^{\prime} \models \tau_{1}\left(\square^{*}(x \Rightarrow(A \wedge B))\right)$. Proofs for rewriting of other classical operators are similar.

Now assume that $\varphi$ is of the form $\square A$, where $A$ is not a literal. Then the transformation, $\tau_{1}\left(\square^{*}(x \Rightarrow \sqcap A)\right.$ ), is given by $\square^{*}(x \Rightarrow \sqcap y) \wedge \tau_{1}\left(\square^{*}(y \Rightarrow A)\right)$. Let $M^{\prime}$ be exactly as $M$, but $\pi\left(s^{\prime}\right)(y)=$ true for all $s^{\prime} \in \mathcal{S}$ such that $\left(s, s^{\prime}\right) \in \mathcal{R}_{i}$ and $\pi(s)(x)=$ true. Let $s$ be any world in $M$. Thus, if $(M, s) \models x$, because $\left(M, s^{\prime}\right) \models y$, for all $\left(s, s^{\prime}\right) \in \mathcal{R}_{i}$, then $\left(M^{\prime}, s\right) \models(x \Rightarrow \dot{i})$; if $(M, s) \not \models x$, then $\left(M^{\prime}, s\right) \not \models x$ and the implication holds at $\left(M^{\prime}, s\right)$. By semantics of $\square^{*}$, $M^{\prime} \models\left(\square^{*}(x \Rightarrow\right.$ i $y)$ ). For all $s \in \mathcal{S}$, if $\left(M^{\prime}, s\right) \models y$ then $\left(M^{\prime}, s\right) \models A$, because $y$ and $A$ are true at the worlds which are are accessible from where $x$ holds. Therefore $\left(M^{\prime}, s\right) \models(y \Rightarrow A)$. If $\left(M^{\prime}, s\right) \not \vDash y$, then the implication is vacuously true. Thus, by semantics of $\square^{*}, M^{\prime} \models \square^{*}(y \Rightarrow A)$. By induction hypothesis, $M^{\prime}$ satisfies the translation of $\square^{*}(x \Rightarrow \square A)$, that is, $M^{\prime} \models \square^{*}(x \Rightarrow \square y) \wedge$ $\tau_{1}\left(\square^{*}(y \Rightarrow A)\right)$. The proofs for other cases of renaming are similar.

Lemma 4. Let $\varphi$ be a formula in $\mathrm{K}_{(n)}$. Let $M=\left\langle\mathcal{S}, \mathcal{R}_{1}, \ldots, \mathcal{R}_{1}, \pi\right\rangle$ be a model. If $M \models \varphi$, then there is a model $M^{\prime}$ such that $M^{\prime} \models \tau_{0}(\varphi)$.

Proof. Let $s_{0} \in \mathcal{S}$, be the initial world in $M$. Suppose $M \models \varphi$. Construct a model $M^{\prime}$ that is identical to $M$, but where $M^{\prime} \models$ start if, and only if, $M^{\prime} \models x$, that is $\pi(s)(x)=$ true if, and only if, $s=s_{0}$, for $s \in \mathcal{S}$. Clearly, $M^{\prime} \models \square^{*}($ start $\Rightarrow x) \wedge \square^{*}(x \Rightarrow \varphi)$. Given this and, by Lemma 3 , it is possible to construct a new model for every application of $\tau_{1}$, then there is a model such that $M^{\prime} \models \square^{*}($ start $\Rightarrow x) \wedge \tau_{1}\left(\square^{*}(x \Rightarrow \varphi)\right)$, that is, $M^{\prime} \models \tau_{0}(\varphi)$.

Thus, a formula is satisfiable if, and only if, its translation into the normal form is satisfiable.

Theorem 1. Let $\varphi$ be a formula in $\mathrm{K}_{(n)}$ and $M$ a model. $M \models \varphi$ if, and only if, there is a models $M^{\prime}$ such that $M^{\prime} \models \tau_{0}(\varphi)$.

Proof. By Lemmas 2 and 4.

## 4 Anti-Prenexing

Anti-prenexing has been used in first-order theorem proving as a step applied before skolemization, in order to achieve a better set of clauses [2]. Similarly to first-order, anti-prenexing in the modal context means that all modal operators are moved inwards the formula as far as possible, whilst preserving satisfiability. In the weakest normal logic, $\mathrm{K}_{(n)}$, that means that we can distribute the necessity operator,$\square$, over conjunctive formulae; and the possibility operator, $\qquad$ over disjunctive formulae. The definition of the anti-prenex normal form is given below.

Definition 7. A modal term is a literal or formula of the form $M_{1} \ldots M_{k} l$, where $l$ is a literal and $M_{i}, 1 \leq i \leq k$, is $[j$ or $\neg$ for some $j \in \mathcal{A}$.

Note that aliteral $l$, which is not preceded by any modal operator, is also a modal term.

Definition 8. Let $\varphi$ and $\psi$ be formula in $\mathrm{WFF}_{\mathrm{K}_{(n)}}$. A formula $\chi$ is in AntiPrenex Normal Form (APNF) if, and only if,

1. $\chi$ is a modal term; or
2. $\chi$ is of the form $\neg \varphi,(\varphi \wedge \psi),(\varphi \vee \psi)$ or $(\varphi \Rightarrow \psi)$, and $\varphi$ and $\psi$ are in APNF;
3. $\chi$ is of the form $\rceil \varphi, \varphi$ is disjunctive, and/or $\varphi$ is in APNF; or
4. $\chi$ is of the form $\neg \varphi, \varphi$ is conjunctive, and/or $\varphi$ is in APNF.

The following lemma shows that any formula can be transformed into APNF.
Lemma 5. Let $\varphi$ be a formula in $\mathrm{K}_{(n)}$ and $M$ a model in $\mathrm{K}_{(n)}$. Then there is a formula $\varphi^{\prime}$ in APNF such that if $M \models \varphi$ then $M \models \varphi^{\prime}$.

Proof. The following schemata are theorems of $\mathrm{K}_{(n)}$ :

1. $\overbrace{}^{i}(\varphi \wedge \psi) \Leftrightarrow(\varpi \varphi \wedge \llbracket \psi)$
2. ${ }^{i} \neg(\varphi \Rightarrow \psi) \Leftrightarrow(\varpi \varphi \wedge \square \neg \psi)$
3.$i \neg(\varphi \vee \psi) \Leftrightarrow($ i $\neg \varphi \wedge$ i $\neg \psi)$
3. $\neg \square \neg(\varphi \Rightarrow \psi) \Leftrightarrow(\boxed{i} \varphi \Rightarrow \neg \square \neg \psi)$
4. $\neg i \neg(\varphi \vee \psi) \Leftrightarrow(\neg i \neg \varphi \vee \neg i \neg \psi)$
5. $\neg \dot{\square}(\varphi \wedge \psi) \Leftrightarrow(\neg \dot{\square} \varphi \vee \neg \psi)$

The transformation into $\mathrm{SNF}_{K}$ consists of two steps: transforming the formulae into anti-prenex, as defined below, and then applying the transformation function given in Subsection 3.1. Firstly, based on the schemata presented in Lemma 5, we define a function $\alpha(\varphi)$, where $\varphi$ is a formula, which produces the anti-prenex normal form of $\varphi$. The base case occurs when the formula $A$ is already in APNF, that is, $A$ is a modal term. In this case, $\alpha(A)=A$. If the main operator is modal, we only apply the transformation function to formula which satisfies the equivalences in Lemma 5, that is, in the following cases:

If we have two consecutive modal operators, the function is applied recursively, where $A$ is of the form $B$ or $\neg B$, for any $j \in \mathcal{A}$ :

$$
\begin{gathered}
\alpha(\boxed{i} A)=\alpha(\sqrt{i}(A)) \\
\alpha(\neg \sqrt{i})=\alpha(\neg \square \alpha(A))
\end{gathered}
$$

If the main operator is a modal operator, but the formula inside its scope is not one of the above, we apply the anti-prenexing function to this formula, that is:

$$
\begin{aligned}
\alpha(i) & =i \alpha(A) \\
\alpha(\neg i A) & =\neg i \alpha(A)
\end{aligned}
$$

When the main operator is classical, the transformation function is also applied recursively. Note that when the polarity of a subformula is negative, we rewrite the formula in order to make this explicit.

$$
\begin{aligned}
\alpha(\neg \neg A) & =\alpha(A) \\
\alpha(A \Rightarrow B) & =\alpha(\neg A) \vee \alpha(B) \\
\alpha(A \wedge B) & =\alpha(A) \wedge \alpha(B) \\
\alpha(A \vee B) & =\alpha(A) \vee \alpha(B)
\end{aligned}
$$

$$
\begin{aligned}
\alpha(\neg(A \Rightarrow B)) & =(\alpha(A) \wedge \alpha(\neg B)) \\
\alpha(\neg(A \wedge B)) & =(\alpha(\neg A) \vee \alpha(\neg B)) \\
\alpha(\neg(A \vee B)) & =(\alpha(\neg A) \wedge \alpha(\neg B))
\end{aligned}
$$

$$
\begin{aligned}
& \alpha(\text { i }(A \wedge B))=\alpha(\square A \wedge \text { i } B) \\
& \alpha(i \neg(A \Rightarrow B))=\alpha(\square A \wedge \square \neg B) \\
& \alpha(\dot{i} \neg(A \vee B))=\alpha(\text { i } \neg A \wedge \square \neg B) \\
& \alpha(\neg i \neg(A \Rightarrow B))=\alpha(i A \Rightarrow \neg i \neg B) \\
& \alpha(\neg i \neg(A \vee B))=\alpha(\neg i \neg A \vee \neg i \neg B) \\
& \alpha(\neg i(A \wedge B))=\alpha(\neg i A \vee \neg i B)
\end{aligned}
$$

The proof that this transformation is correct and satisfiability can be obtained as in Subsection 3.2 for translation into SNF $_{K}$ and will not be presented here.

As an example, the APNF of $\dot{\square}(a \wedge \dot{\square}(b \wedge \boxed{i}))$ is given by:

$$
\begin{aligned}
& \alpha(i(a \wedge i(b \wedge i c)))= \\
& =\alpha(i a \wedge i \square(b \wedge i c)) \\
& =\alpha(\square a) \wedge \alpha(i \quad i(b \wedge i c)) \\
& =\hbar a \wedge \alpha(\square \alpha(\square(b \wedge \square c))) \\
& =i a \wedge \alpha(i \alpha(\square b \wedge i \square c)) \\
& =\square a \wedge \alpha(i(\alpha(\dot{i}) \wedge \alpha(i \quad i c))) \\
& =\square a \wedge \alpha(\dot{i}(\dot{i} b \wedge \dot{i} c)) \\
& =i a \wedge \alpha(i \pi b \wedge i n c) \\
& =i a \wedge \alpha(i \quad b) \wedge \alpha(i) c) \\
& =i a \wedge i \pi b \wedge i n c
\end{aligned}
$$

whose transformation into the normal form is:

$$
\begin{gathered}
\square^{*}(\text { start } \Rightarrow x) \wedge \square^{*}(x \Rightarrow \square a) \wedge \square^{*}(x \Rightarrow \square y) \wedge \square^{*}(y \Rightarrow i b) \wedge \\
\square *(x \Rightarrow i z) \wedge \square^{*}(z \Rightarrow \square w) \wedge \square^{*}(w \Rightarrow i c) .
\end{gathered}
$$

## 5 Simplification Rules

The anti-prenexing pre-processing of a formula may result in fewer or shorter clauses. For instance, consider the formula $i(a \wedge b)$. Transformation into SNF $_{K}$ results in four clauses $\left(\square^{*}(\right.$ start $\Rightarrow x), \square^{*}(x \Rightarrow \square y), \square^{*}($ true $\Rightarrow \neg y \vee a)$, and $\square^{*}($ true $\Rightarrow \neg y \vee b)$ ), whilst transformation into the normal form preceded by anti-prenexing results in three clauses $\left(\square^{*}(\right.$ start $\Rightarrow x), \square^{*}(x \Rightarrow 母 a)$, and $\square^{*}(x \Rightarrow \square b)$ ). However, this is not always the case. Depending on the nesting of modal operators in the original formula, the number of clauses generated after anti-prenexing and translation into $\mathrm{SNF}_{K}$ can be significantly larger than by applying the transformation into $\mathrm{SNF}_{K}$ alone. The reason is that the modal operator that had appeared only once in the formula now has several copies distributed over subformulae.

However, when applied together with simplification, anti-prenexing may reduce the number of clauses, by collapsing of nested modal operators in the original formula. Obviously, this depends on the particular normal modal logic we are considering. We discuss in this section the simplification rules that could be applied together with anti-prenexing, before transformation into $\mathrm{SNF}_{K}$, in the case of $\operatorname{KTD}^{(n)}{ }_{(n)}$ and $\mathrm{KD45}_{(n)}$. The first normal modal logic, also known as $\mathrm{S5}_{(n)}$ - the logic of knowledge for multiple agents - is axiomatisable by the schemata $\mathbf{K}, \mathbf{T}, \mathbf{D}, \mathbf{4}$, and $\mathbf{5}$ and the rules of inference: modus ponens (from $\vdash \varphi$ and $\vdash(\varphi \Rightarrow \psi)$ infer $\vdash \psi)$ and modal necessitation rule (from $\vdash \varphi$ infer $\vdash i \varphi$ ). The logics $\mathrm{KD}^{2} 5_{(n)}$, known as the logic of belief for multiple agents, is axiomatisable by the schemata $\mathbf{K}, \mathbf{D}, \mathbf{4}$, and $\mathbf{5}$ and the rules of inference modus ponens and modal necessitation rule. As the schemata $i \quad i \varphi \Leftrightarrow i \varphi, i \neg i \varphi \Leftrightarrow \neg i \varphi$, $\neg i \neg i \varphi \Leftrightarrow i \varphi, \neg i \underline{i} \varphi \Leftrightarrow \neg \varphi$ are valid in $\operatorname{KTD}_{2} 5_{(n)}$ and in $\operatorname{KD45}_{(n)}$, we extend the anti-prenexing function in the obvious way:

$$
\begin{aligned}
& \alpha(\text { 国 } \varphi \text { ) }=\alpha(\text { 国 } \varphi) \\
& \alpha(\text { 国 } \neg \varphi)=\alpha(\neg \text { 国 } \varphi) \\
& \alpha(\neg \square \neg)=\alpha(\square \varphi) \\
& \alpha(\neg \text { ® } \varphi)=\alpha(\neg \text { 国 })
\end{aligned}
$$

We note that we only apply this simplification when the modal operators have the same index．Other simplification rules could also be introduced，but we chose not to do this and，instead，preserving some of the structure of the formula．Using these simplification rules，the anti－prenex normal form of the previous example， i．e．$i(a \wedge i(b \wedge i c)$ ，is $\square a \wedge i b \wedge$ i $c$ ，which has the same size as the original formula．The translation into $\mathrm{SNF}_{K}$ results，however，in four clauses． Table 1 show the three transformations for comparison．

|  |  |  |
| :---: | :---: | :---: |
| $\mathrm{SNF}_{K}$ | $\mathrm{AP}+\mathrm{SNF}_{K}$ | $\mathrm{AP}+\mathrm{SIMP}+\mathrm{SNF}_{K}$ |
|  |  |  |
| 1．start $\Rightarrow x$ | 1．start $\Rightarrow x$ | 1．start $\Rightarrow x$ |
| 2．$x \Rightarrow$ ¢ | 2．$x \Rightarrow$ 亿 $a$ | 2．$x \Rightarrow$ ® $a$ |
| 3．true $\Rightarrow \neg y \vee a$ | 3．$\quad x \Rightarrow$ ¢ | 3．$\quad x \Rightarrow$ ¢ |
| 4．$y \Rightarrow$ ¢ | 4．$y \Rightarrow$ i $b$ | 4．$y \Rightarrow$ ¢ |
| 5．true $\Rightarrow \neg z \vee b$ | 5．$\quad x \Rightarrow$ ® |  |
| 6．$z \Rightarrow$ ¢ | 6．$z \Rightarrow$ ¢ $w$ |  |

Table 1．Translation（from left to right）without Anti－Prenexing，after Anti－Prenexing， and after Anti－Prenexing and Simplification．

Note that no simplification rule could be applied to the original formula． By moving the modal operators inwards the formula，simplification could be applied，resulting in fewer and shorter clauses．

## 6 Prenexing

Similarly to first－order logic，prenexing in the modal context means to pull modal operators as far as possible outwards the formula．It is well－known that formulae in KTD45 ${ }_{(1)}$ can be transformed into a formula without nesting of modal opera－ tors（see［5］，for instance）．As we are interested in a more general form of prenex－ ing than that given for $\mathrm{KTD45}_{(1)}$ ，we say that a formula is in prenex normal form if it corresponds to the inverse of the transformation into anti－prenexing．Thus，
the transformation is justified by the same equivalences appearing in Lemma 5. Our definition of the prenexing function is similar to that given in Section 4 and will not be presented here. Instead, in this section, we give the motivation for using both techniques together with simplification for KTD45 ${ }_{(n)}$ and KD45 ${ }_{(n)}$.

When a formula $\varphi$ is transformed into APNF, the nesting of modal operators is made explicit and can be easily simplified. On the other hand, several copies of a modal operator may now appear in the formula. By performing the transformation into prenex normal form, after anti-prenexing and simplification, we try to remove such copies and make the formula shorter. We note that the order in which the transformations are applied is important. Consider, for instance, the formula given in previous examples, that is, $i(a \wedge i(b \wedge \neg i \neg c))$. This formula is in prenex normal form, as we cannot apply any of the equivalences given in Lemma 5 to move the modal operators outwards the formula. However, if we apply anti-prenexing with simplification, we obtain, as seen before, the formula $i a \wedge i b \wedge i c$. The result of applying the prenex function is $i(a \wedge b \wedge c)$, which is shorter than both the original formula and the one obtained after anti-prenexing with simplification. In this case, however, the transformation into $\mathrm{SNF}_{K}$ results in one more clause. We give below an example where the number of clauses is smaller than that produced by the other methods without prenexing:

As a final example, consider the formula $\neg i \neg(i) a \wedge \square b)$, which is already in APNF, as the modal operator $\neg \square \neg$ cannot be distributed over conjunctions. Also, no simplification rule can be applied to the formula. After applying prenexing, however, we obtain $\neg \square \neg i(a \wedge b)$, which simplifies to $i(a \wedge b)$. We do not apply anti-prenexing again, which would result in a shorter translation into $\mathrm{SNF}_{K}$, as discussed at the beginning of Section 5. Nevertheless, the resulting formula is half the size of the original one and the set of clauses is also smaller.

## 7 Experimental Results

The examples given here have only the purpose of illustrating the techniques. We cannot prove, in general, that by applying those techniques we will obtain a better set of clauses. In order to have a measure of how anti-prenexing and prenexing behave in comparison to translation to $\mathrm{SNF}_{K}$ alone, we have performed tests using formulae from [4].

The program takes a modal formula and returns its size and number of literals. It also returns the size and number of literals after transforming the formula into $\mathrm{SNF}_{K}$ alone, into $\mathrm{SNF}_{K}$ preceded by anti-prenexing, and into $\mathrm{SNF}_{K}$ preceded by anti-prenexing with simplification. We are currently working on the implementation of prenexing.

Table 2 shows the output from running the program over formulae from the benchmark s4_45_p.txt, which contains problems in $\mathrm{KT4}_{(1)}$ which are provable in both $\mathrm{KT}_{(1)}$ and $\mathrm{KTD}^{2} 5_{(1)}$. For each problem, identified in the first column, we present the total size of the formula (Size) and the number of different literals (Lits). Columns 2 and 3 refer to the original formula. Columns 4 and 5 show the result for transformation into $\mathrm{SNF}_{K}$ alone. Columns 6 to 8 are related to antiprenexing without simplification, where the first two columns are the size of the problem after transforming into anti-prenexing, and the other two columns are the result of transforming into $\mathrm{SNF}_{K}$. The last four columns contain the result for anti-prenexing together with simplification: their contents are similar to those for anti-prenexing without simplification. The table shows that transformation into $\mathrm{SNF}_{K}$ preceded by anti-prenexing with simplification perform better than the other two methods. Other experimental results can be found in Appendix A.

## 8 Conclusions

In this paper we have presented an algorithm for transforming any normal modal formula into a normal form. This can be done because the transformation is based on valid schemata of the weakest of the normal modal logics, namely $\mathrm{K}_{(n)}$. Also, we investigate how the use of anti-prenexing and prenexing can help in obtaining a better transformation. Combined with simplification rules, these methods seem to produce smaller clause sets for problems from some normal logics.

There is no way of defining which is the best normal form, in general. Here we focused on the size of the transformed problem as a measure for determining whether the transformation is good. However, we also intend to investigate other parameters, as for instance the number of clauses and their sizes, as well as how efficiently a real theorem-prover responds to those different transformations. As anti-prenexing with simplification moves the modal operators inwards the formula, those operators are usually applied to simpler formulae, indicating that we could have less resolution steps applied to a clause set.

Simplification is an important step in the translation algorithm, but, as discussed before, it cannot be applied to all normal modal logics. We have shown the simplification rules for $\mathrm{KTD}^{2} 5_{(n)}$ and $\mathrm{KD45}_{(n)}$. The equivalences i $\neg i \varphi \Leftrightarrow \neg i \varphi$ and $\neg i \neg i \varphi \Leftrightarrow i \varphi$ are also valid in $\mathrm{K}_{4} 5_{(n)}$ and $\mathrm{KT}_{(n)}$ (also known as $\mathrm{S}_{(n)}$ ), so the formula resulting from anti-prenexing can be simplified, but not at the same extent as those of $\operatorname{KTD}^{2} 5_{(n)}$ and KD45 $_{(n)}$. The other modal logics do not admit simplification rules for collapsing of nested operators. In these cases, as our experimental results show, applying anti-prenexing does not seem to be worthwhile. We are currently working on the complexity of the transformation in order to determine precisely when anti-prenexing and prenexing of a formula would result in a better set of clauses. That is, the techniques shown here could be used selectively in a similar way as renaming is used [7].

We are currently working on the implementation of the prenexing algorithm. We believe that anti-prenexing together with prenexing and simplification will give us the best result for formulae in $\mathrm{KTD}^{\left(5_{(n)}\right.}$ and $\mathrm{KD45}_{(n)}$. We hope that the same combination will give us better results for the other logics.

Current work also involves the development of the resolution-based methods for each logic. Our intention is that a uniform approach to deal with those logics - from the designing of the normal forms up to the whole proof-method - will facilitate the task of validity checking for combinations of those logics.
