The Constrained Multiple Sequence Alignment problem is to align a set of sequences of maximum length  $n$  subject to a given constrained sequence, which arises from some knowledge of the structure of the sequences. This paper presents new algorithms for this problem, which are more efficient in terms of time and space (memory) than the previous algorithms<sup>15</sup>, and with a worst-case guarantee on the quality of the alignment. Saving the space requirement by a quadratic factor is particularly significant as the previous  $O(n^4)$ -space algorithm has limited application due to its huge memory requirement. Experiments on real data sets confirm that our new algorithms show improvements in both alignment quality and resource requirements.

*Keywords:* Multiple Sequence Alignment; Approximation algorithm.

### 1. Introduction

Multiple sequence alignment (MSA) is one of the problems in computational biology that have been studied extensively<sup>2,6,10,8,3,13,14</sup>. Roughly speaking, given a set of  $k \geq 2$  sequences, the MSA problem is to align similar subsequences in the same region. From the computational point of view, the optimal alignment of two sequences can be found in  $O(n^2)$  time, where  $n$  is the length of the longer sequence. Yet, for three or more sequences, it has been proved that finding the optimal alignment is NP-hard<sup>2,17</sup>, i.e., intractable<sup>a</sup>. In the literature, there are a number of MSA algorithms that attempt to approximate the optimal alignments, some of them can provide a worst-case approximation ratio<sup>1,5,12</sup>, while some others work well in practice<sup>11,16</sup>. Notice that with all these algorithms, users (biologists) can only control the alignment results by adjusting parameters like the scoring function and gap penalty. In other words, users could not incorporate their knowledge of the functionalities or structures of the input sequences, which is indeed very useful for accurate and biologically meaningful alignment. This naturally triggers the studies of sequence alignment that allows users to provide additional constraints.

Tang *et al.*<sup>15</sup> were the first to investigate the MSA problem with an additional input of a constrained sequence, which imposes a structure on the alignment by requiring every character in the constrained sequence to appear in an entire column

<sup>a</sup>There are several possible ways to define the optimal alignment. In this paper we adopt the widely-used *Sum-of-Pair (SP)* score, which asks for an alignment that minimizes the sum of the alignment cost of all pairs of sequences.

in the alignment of the multiple sequences. As an example, Tang *et al.* considered the alignment of *RNase* sequences. Such sequences are all known to contain three active-site residues His(H), Lyn(K), His(H) that are essential for RNA degrading. Therefore, one would expect that in an alignment of RNase sequences, each of these three residues should be aligned in the same column, i.e., an alignment satisfying the constrained sequence “HKH”.

Tang *et al.*<sup>15</sup> presented the first algorithm for finding an optimal constrained sequence alignment for two sequences; both the time and space (memory) requirements of the algorithm are  $O(\alpha n^4)$ , where  $\alpha$  is the length of the constrained sequence. For aligning  $k \geq 3$  sequences, they gave a heuristic algorithm (called progressive alignment algorithm) with time and space requirements being  $O(\alpha k n^4)$  and  $O(\alpha n^4)$ , respectively. When applied to aligning multiple RNase sequences, this algorithm produces satisfactory alignments. Yet the application of the algorithm is limited as the memory requirement is too large and it runs too long. For example, for aligning sequences of length 250 with a constraint of length 3, the memory requirement already exceeds 15 Gigabytes. Nowadays ordinary workstations are equipped with at most 4 Gigabytes.

This paper attempts to improve the results of Tang *et al.* from a theoretical as well as a practical point of view. For pair-wise alignment, we give a new algorithm for finding the optimal constrained alignment that uses  $O(\alpha n^2)$  time and  $O(\alpha n^2)$  space. Based on this result, we can immediately improve the time and space complexities of the progressive alignment algorithm by a quadratic factor. Furthermore, we give an algorithm, called center-star, for constrained multiple sequence alignment with worst-case performance guarantee; more precisely, for aligning  $k$  sequences, the new algorithm can produce an alignment that approximates the optimal alignment within a factor of  $(2 - \frac{2}{k})$ . This algorithm adopts the framework of Gusfield’s (unconstrained) multiple sequence alignment algorithm<sup>5</sup>. The time and space complexities of the new algorithm are respectively  $O(Ckn^2)$  and  $O(n^2)$ , where  $C$  is the total number of occurrences of the constrained sequence in all sequences. The improved memory requirement allows us to handle sequences with thousands of characters on ordinary workstations. See Table 1 for a summary of these results.

We have implemented all the algorithms mentioned above and tested them with several real data sets. In all data sets, the center-star algorithm shows improvement in all aspects. In particular, the quality of the alignment is 13% to 30% better, while the memory requirement is at most one-percent of Tang *et al.*’s algorithm. Results

	Time complexity	Space complexity	Approximation Ratio

are briefly summarized in Table 2. More details will be given in Section 6.

The rest of this paper is organized as follows. Section 2 defines the constrained sequence alignment problem, and Section 3 presents a new algorithm that computes the optimal constrained pair-wise sequence alignment. Section 4 presents algorithms for *constrained multiple sequence alignment* (CMSA). In Section 5, an approximation algorithm is given with an approximation ratio  $(2 - \frac{2}{k})$ . We report empirical results of our developed CMSA tools in Section 6. Finally, in Section 7, we conclude this paper by giving some further research directions in CMSA.

## 2. Preliminaries

Let  $\Sigma$  be the set of characters (residues),  $S = \{S_1, S_2, \dots, S_k\}$  be a set of  $k$  sequences, with maximum length  $n$ , over  $\Sigma$ . Let  $S_i[x..y]$  denote the substring of  $S_i$  from the  $x$ -th character to the  $y$ -th character of  $S_i$ , where  $1 \leq x \leq y \leq n$ . In particular, let  $S_i[x]$  denote the  $x$ -th character in the sequence  $S_i$ .

We define the *pair-wise sequence alignment* of two sequences  $S_1$  and  $S_2$  as two equal-length sequences  $S'_1$  and  $S'_2$  such that  $|S'_1| = |S'_2| = n'$ , and removing all space characters “—” from  $S'_1$  and  $S'_2$  gives  $S_1$  and  $S_2$ , respectively. For a given distance function  $\delta(x, y)$  which measures the *mutation distance* between two characters, where  $x, y \in \Sigma \cup \{-\}$ , the *pair-wise score* of two length- $n'$  sequences  $S'_1$  and  $S'_2$  is defined as  $\sum_{1 \leq x \leq n'} \delta(S'_1[x], S'_2[x])$ . In the multiple sequence alignment (MSA) problem, we are given  $k$  sequences  $S = \{S_1, S_2, \dots, S_k\}$ , an MSA is an *alignment matrix*  $A$ , with  $k$  rows and  $n' (\geq n)$  columns, such that removing space characters from the  $i$ -th row of  $A$  gives  $S_i$  for  $1 \leq i \leq k$ . We denote by  $A[x, y]$  the character at the  $x$ -th row and  $y$ -th column of  $A$ . The *sum-of-pair (SP)* score of an MSA  $A$  is defined as the sum of the pair-wise scores of all pairs of the sequences, i.e.,  $\sum_{1 \leq p < q \leq k} \sum_{1 \leq y \leq n'} \delta(A[p, y], A[q, y])$ . It has been shown that finding the alignment

matrix with the minimum sum-of-pair alignment score is NP-complete<sup>17,2</sup>.

In the *constrained multiple sequence alignment problem (CMSA)*, we are given, in addition to the inputs of the MSA problem, a constrained sequence  $P = (P[1], P[2], \dots, P[\alpha])$ , where  $P$  is a common subsequence of all  $S_i \in \{S_1, S_2, \dots, S_k\}$ . The solution of a CMSA problem is a *constrained alignment matrix*  $A$  which is an alignment matrix such that each character in  $P$  appears in an entire column of  $A$  and also in the same order, i.e., there exists a list of integers  $\{r_1, r_2, \dots, r_\alpha\}$  where  $1 \leq r_1 < r_2 < \dots < r_\alpha \leq n'$ , such that for all  $1 \leq i \leq k$  and all  $1 \leq \gamma \leq \alpha$ , we have  $A[i, r_\gamma] = P[\gamma]$ .

Consider a constrained alignment matrix  $A$  for  $S = \{S_1, S_2, \dots, S_k\}$  and the constrained sequence  $P$ . Denote by  $sp\_score(A)$  the SP score of the constrained alignment matrix  $A$ . Let  $A_S^*$  be the optimal constrained alignment matrix for  $S$  and  $A_S'$  be the constrained alignment matrix derived by some approximation algorithm. The approximation algorithm is said to have an approximation ratio  $\phi$  if  $\frac{sp\_score(A_S')}{sp\_score(A_S^*)} \leq \phi$  for all  $S$  and  $P$ .

### 3. Constrained Pair-wise Sequence Alignment (CPSA)

#### 3.1. Problem definition

The *constrained pair-wise sequence alignment (CPSA)* problem is a special case for CMSA problem with  $k = 2$ . Given two sequences  $S_1$  and  $S_2$ , a constrained sequence  $P$  (with length  $\alpha$ ) and a distance function  $\delta$ , the problem is to compute an optimal CPSA,  $(S_1', S_2')$ , such that  $|S_1'| = |S_2'| = |n'|$ , and  $\sum_{1 \leq i \leq n'} \delta(S_1'[i], S_2'[i])$  is minimized subject to  $P[\gamma] = S_1'[r_\gamma] = S_2'[r_\gamma]$  for some  $r_\gamma$ ,  $1 \leq \gamma \leq \alpha$  and  $1 \leq r_1 < r_2 < \dots < r_\alpha \leq n'$ . Note that removing all spaces in  $S_1'$  and  $S_2'$  gives  $S_1$  and  $S_2$  respectively.

#### 3.2. Optimal Constrained Pair-wise Sequence Alignment

Tang *et al.*<sup>15</sup> presented an algorithm to compute the optimal constrained pair-wise alignment with time and space complexities  $O(\alpha n^4)$  and  $O(\alpha n^4)$ , respectively. This algorithm first computes the  $O(n^4)$  pair-wise alignment scores of all substrings in  $S_1$  and all substrings in  $S_2$  and then further determines the best positions such that the constrained characters are aligned. The overall time complexity is  $O(\alpha n^4)$ . To improve the time complexity, our algorithm takes into consideration the constrained alignment as we compute the alignment score. This approach makes it not necessary to consider all the pair-wise alignments between every pair of substrings of  $S_1$  and  $S_2$ , and thus, facilitates the reduction in the time complexity.

Below we show how to compute the sum-of-pair score of the optimal CPSA by dynamic programming and how to obtain the alignment by backtracking through the path of computation of the score. Recall that for any sequence  $S$ ,  $S[x..y]$  denotes the substring of  $S$  starting at the  $x$ -th character and ending at the  $y$ -th character of  $S$ . The dynamic programming computes the optimal CPSA incrementally by con-

sidering the pair-wise alignments of  $S_1[1..1]$  with  $S_2[1..1]$ ,  $\dots$ ,  $S_1[1..i]$  with  $S_2[1..j]$  and so on, for  $1 \leq i \leq |S_1|$  and  $1 \leq j \leq |S_2|$ .

We denote by  $D(i, j, \gamma)$  the optimal constrained pair-wise sequence alignment score of sequences  $S_1[1..i]$  and  $S_2[1..j]$  with constrained characters  $P[1..\gamma]$  matched. In particular,  $D(n_1, n_2, \alpha)$  is the optimal CPSA score of  $S_1$  and  $S_2$  with respect to the constrained sequence  $P$ , where  $|S_1| = n_1$ ,  $|S_2| = n_2$  and  $|P| = \alpha$ . The following theorem gives a recurrence formula for  $D(i, j, \gamma)$  in terms of  $D(i', j', \gamma')$  where  $i' \leq i$ ,  $j' \leq j$ , and  $\gamma' \leq \gamma$ .

**Theorem 1.** For any  $0 \leq i \leq n_1, 0 \leq j \leq n_2$  and  $0 \leq \gamma \leq \alpha$ ,

$$D(i, j, \gamma) = \min \begin{cases} D(i-1, j-1, \gamma-1) + \delta(S_1[i], S_2[j]) & \text{if } S_1[i] = S_2[j] = P[\gamma], \\ D(i-1, j-1, \gamma) + \delta(S_1[i], S_2[j]) & \text{if } i, j > 0, \\ D(i-1, j, \gamma) + \delta(S_1[i], -) & \text{if } i > 0, \\ D(i, j-1, \gamma) + \delta(-, S_2[j]) & \text{if } j > 0, \end{cases}$$

with boundary conditions  $D(0, 0, 0) = 0$ ,  $D(i, 0, \gamma) = \infty$  for  $\gamma \geq 1$ ,  $0 \leq i \leq n_1$ , and  $D(0, j, \gamma) = \infty$  for  $\gamma \geq 1$ ,  $0 \leq j \leq n_2$ .

**Proof.** There are four cases to align  $\{S_1[1..i], S_2[1..j]\}$  with respect to  $P[1..\gamma]$ ,

- If  $S_1[i] = S_2[j] = P[\gamma]$ , we can align  $S_1[i]$  and  $S_2[j]$  while aligning  $\{S_1[1..(i-1)], S_2[1..(j-1)]\}$  with  $P[1..(\gamma-1)]$  matched. Then, the score is  $D(i-1, j-1, \gamma-1) + \delta(S_1[i], S_2[j])$ .
- If  $i, j > 0$ , we can align  $S_1[i]$  and  $S_2[j]$  while aligning  $\{S_1[1..(i-1)], S_2[1..(j-1)]\}$  with  $P[1..\gamma]$  matched. Then the score is  $D(i-1, j-1, \gamma) + \delta(S_1[i], S_2[j])$ .
- If  $i > 0$ , we can align  $S_1[i]$  with a space while aligning  $\{S_1[1..(i-1)], S_2[1..j]\}$  with  $P[1..\gamma]$  matched. Then the score is  $D(i-1, j, \gamma) + \delta(S_1[i], -)$ .
- If  $j > 0$ , we can align  $S_2[j]$  with a space while aligning  $\{S_1[1..i], S_2[1..(j-1)]\}$  with  $P[1..\gamma]$  matched. Then the score is  $D(i, j-1, \gamma) + \delta(-, S_2[j])$ .

The alignment to be chosen is the one such that the new score is minimum. Therefore,  $D(i, j, \gamma)$  can be computed by taking the minimum of the above four values  $\square$

Based on Theorem 1, we can compute the sum-of-pair score of the optimal CPSA using dynamic programming (see Algorithm 1). After filling in the three dimensional table  $D(i, j, \gamma)$ , we can obtain the CPSA by backtracking through the computation path from  $D(n_1, n_2, \alpha)$  to  $D(0, 0, 0)$ . Let  $S'_1$  and  $S'_2$  be the aligned sequence for  $S_1$  and  $S_2$ , respectively. Initially, set  $S'_1$  and  $S'_2$  to two empty strings, and start backtracking from  $D(n_1, n_2, \alpha)$ . If  $D(i, j, \gamma)$  is computed from  $D(i-1, j-1, \gamma)$  or  $D(i-1, j-1, \gamma-1)$ , prepend  $S_1[i]$  and  $S_2[j]$  to  $S'_1$  and  $S'_2$ , respectively. If  $D(i, j, \gamma)$  is computed from  $D(i-1, j, \gamma)$ , prepend  $S_1[i]$  and a space to  $S'_1$  and  $S'_2$ , respectively; similarly, if  $D(i, j, \gamma)$  is computed from  $D(i, j-1, \gamma)$ , prepend a space and  $S_2[j]$  to  $S'_1$  and  $S'_2$ , respectively. Repeat backtracking until reaching  $D(0, 0, 0)$ , and  $(S'_1, S'_2)$  is the optimal constrained sequence alignment of  $\{S_1, S_2\}$  with  $P$  matched.

**Theorem 2.** The optimal constrained pair-wise alignment can be computed in both  $O(\alpha n_1 n_2)$  time and space, where  $|S_1| = n_1$ ,  $|S_2| = n_2$  and  $|P| = \alpha$ .

**Proof.** The 3-dimensional table  $D$  is of size  $((n_1 + 1) \times (n_2 + 1) \times (\alpha + 1))$ . The computation of each entry  $D(i, j, \gamma)$  needs only the values of  $D(i-1, j-1, \gamma-1)$ ,

**Algorithm 1:** Dynamic programming algorithm for the optimal CPSA score

---

```

begin
  // Initialization:
  Initialize  $D(0, 0, 0)$ ,  $D(i, 0, \gamma)$ , and  $D(0, j, \gamma)$ , for  $0 \leq i \leq n_1$ ,  $0 \leq j \leq n_2$ ,
  and  $1 \leq \gamma \leq \alpha$ , according to Theorem 1.
  // Dynamic Programming:
  for  $\gamma = 0$  to  $\alpha$  do
    for  $i = 0$  to  $n_1$  do
      for  $j = 0$  to  $n_2$  do
        If  $D(i, j, \gamma)$  is not initialized, compute  $D(i, j, \gamma)$  according to
        Theorem 1 in terms of  $D(i-1, j-1, \gamma-1)$ ,  $D(i-1, j-1, \gamma)$ ,
         $D(i-1, j, \gamma)$  and  $D(i, j-1, \gamma)$ .
  end

```

---

$D(i-1, j-1, \gamma)$ ,  $D(i-1, j, \gamma)$  and  $D(i, j-1, \gamma)$ , thus, each  $D(i, j, \gamma)$  can be computed in constant time. Therefore, the optimal CPSA score of two sequences of lengths  $n_1$  and  $n_2$  and constrained sequence  $P$  of length  $\alpha$  can be computed in  $O(\alpha n_1 n_2)$  time. On the other hand, in each step of the backtracking from  $D(n_1, n_2, \alpha)$  to  $D(0, 0, 0)$ , at least one of the indices  $i$ ,  $j$  or  $\gamma$  is decreased by one. Thus, there are at most  $(\alpha + n_1 + n_2)$  steps. Notice that each step takes constant time. Therefore, the backtracking takes  $O(\alpha + n_1 + n_2)$  time. Thus, the whole algorithm takes  $O(\alpha n_1 n_2)$  time. Table  $D$  has  $O(\alpha n_1 n_2)$  entries; each entry  $D(i, j, \gamma)$  requires constant amount of space (for storing the alignment score and the direction of the computation path). Therefore, the algorithm requires  $O(\alpha n_1 n_2)$  space. Thus, the theorem follows.  $\square$

**Remarks:** It is easy to see that computation of scores for row  $i$  (column  $j$ , resp.) only depends on that for row  $i-1$  (column  $j-1$ , resp.), hence, the optimal score can be computed in  $O(\alpha \min(n_1, n_2))$  space. By exploiting the idea of Hirschberg's algorithm<sup>7</sup>, we can recover the alignment in  $O(\alpha \min(n_1, n_2))$  space while maintaining the time complexity.

#### 4. Constrained Multiple Sequence Alignment (CMSA)

In this section, we study the constrained multiple sequence alignment problem. In Section 4.1, we reduce the time and space complexities of the progressive CMSA heuristic algorithm<sup>15</sup> presented by Tang *et al.* from  $O(\alpha k n^4)$  to  $O(\alpha k^2 n^2)$ . In Section 4.2, we show an algorithm that computes the optimal CMSA in  $O(\alpha n^k)$  time using the sum-of-pair score.

##### 4.1. Improved progressive CMSA algorithm

Tang *et al.*<sup>15</sup> presented an  $O(\alpha k n^4)$  time and  $O(\alpha n^4)$  space progressive heuristic algorithm for the CMSA problem for a set of  $k$  sequences of length at most  $n$  and a constrained sequence  $P$  of length  $\alpha$ . In Tang *et al.*'s algorithm, a  $k \times k$  distance matrix of the  $k$  sequences is constructed, where the  $(i, j)$  entry represents

the pair-wise sequence alignment score of  $S_i$  and  $S_j$  (note that this alignment score does not consider the constrained sequence  $P$ ). A minimum spanning tree (MST) is then constructed using the *Kruskal algorithm*<sup>4</sup> based on the distance matrix of these sequences. Sequences are then progressively aligned using the CPSA algorithm in the order of the construction of MST. This algorithm performs exactly  $(k - 1)$  constrained pair-wise sequence alignments. By using the constrained pair-wise alignment algorithm described in Section 3.2, the time and space complexities can be improved from  $O(\alpha kn^4)$  and  $O(\alpha n^4)$  to  $O(\alpha k^2 n^2)$  and  $O(\alpha n^2)$ , respectively.

#### 4.2. An algorithm for the optimal CMSA

In this section, we extend the optimal CPSA algorithm described in Section 3.2 to  $k$  sequences. This involves the construction of a  $(k + 1)$ -dimensional matrix  $D$ , which takes  $O(\alpha n^k)$  time and space. More precisely, let the multi-dimensional array  $D(i_1, i_2, \dots, i_k; \gamma)$  be the optimal CMSA score matrix for  $\{S_1[1..i_1], S_2[1..i_2], \dots, S_k[1..i_k]\}$  with  $P[1..\gamma]$  aligned in  $\gamma$  columns. Then the optimal alignment score for  $\{S_1 \dots S_k\}$  with respect to the constrained sequence  $P$  is given by  $D(n_1, n_2, \dots, n_k; \alpha)$ , where  $n_i = |S_i|$  for  $1 \leq i \leq k$ .  $D(i_1, i_2, \dots, i_k; \gamma)$  can be computed by the following recurrence,

$$(i) \ D(\{0\}^k; 0) = 0, \ D(i_1, i_2, \dots, i_k; \gamma) = \infty \text{ if } \gamma \geq 1 \text{ and some but not all of } i_j\text{'s equal zero;}$$

$$(ii) \ D(i_1, i_2, \dots, i_k; \gamma) =$$

$$\min \left\{ \begin{array}{l} D(i_1 - 1, i_2 - 1, \dots, i_k - 1; \gamma - 1) + \delta(S_1[i_1], S_2[i_2], \dots, S_k[i_k]) \\ \text{if } S_1[i_1] = S_2[i_2] = \dots = S_k[i_k] = P[\gamma], \\ \min_{\epsilon \in \{0,1\}^k - \{0\}^k} \left\{ \begin{array}{l} D(i_1 - \epsilon_1, i_2 - \epsilon_2, \dots, i_k - \epsilon_k; \gamma) \\ + \delta(\epsilon_1 S_1[i_1], \epsilon_2 S_2[i_2], \dots, \epsilon_k S_k[i_k]) \end{array} \right\} \end{array} \right\}$$

where  $\epsilon_j = 0$  or  $1$ ,  $\epsilon_j S_j[i_j]$  with  $\epsilon_j = 0$  representing a space character, and  $\delta(x_1, \dots, x_k) = \sum_{1 \leq i < j \leq k} \delta(x_i, x_j)$ .

Based on the above recurrence, we have a dynamic programming formulation that computes the optimal CMSA for multiple sequences, which is a generalization of the dynamic programming formulation for the CPSA problem. Practically, Lipman *et al.*<sup>9</sup> noted that the optimal CMSA can be computed for less than 6 short sequences of length at most 200. In the following section, we present an approximation algorithm for the CMSA problem.

### 5. An Approximation Algorithm for CMSA

Gusfield<sup>5</sup> showed that the center-star algorithm (the idea of center-star originates from Wong<sup>18</sup>) has an approximation ratio  $(2 - \frac{2}{k})$  for the unconstrained multiple sequence alignment problem. Based on the center-star approximation algorithm, we derive an approximation algorithm for CMSA that yields an approximation ratio  $(2 - \frac{2}{k})$ . This algorithm runs in  $O(Ckn^2)$  time, where  $C$  is the total number of occurrences of the constrained sequence  $P$  in all sequences. Throughout this section, we assume that the distance function  $\delta(x, y)$  follows the *triangle inequality*, i.e.,  $\delta(x, y) \leq \delta(x, z) + \delta(z, y)$ , for any  $x, y, z \in \Sigma \cup \{-\}$ , and  $\delta(-, -) = 0$ .

### 5.1. The center-star alignment approximation for CMSA

For a set of  $k$  sequences  $S = \{S_1 \dots S_k\}$ , the *center sequence*  $S_c \in S$  is the sequence such that the sum of constrained pair-wise alignment scores to the other  $(k - 1)$  sequences is minimized, with the additional constraint that  $P$  must appear in the same list of positions of  $S_c$  in every constrained pair-wise alignment of  $S_c$  with  $S_j$ , where  $j \neq c$ . The *star-sum score* of a CMSA with respect to a center sequence  $S_c$  is the sum of pair-wise score of  $S_c$  with all  $S_j \in S - \{S_c\}$ . The constrained center-star approximation algorithm is to find the CMSA and its center sequence  $S_c$  such that the star-sum score with respect to  $S_c$  is minimized. The algorithm can be summarized below,

- (i) For each  $S_i$  in  $S$ , treat  $S_i$  as the center sequence and for each list of positions  $(r_1, r_2, \dots, r_\alpha)$  that  $S_i$  is aligned with  $P$ , i.e.,  $P[\gamma] = S_i[r_\gamma] \forall 1 \leq \gamma \leq \alpha$ , align all other  $S_j$  with  $S_i$  at the positions specified by  $(r_1, r_2, \dots, r_\alpha)$ .
- (ii) Find the  $S_c$  and  $(r_1, r_2, \dots, r_\alpha)$  with the minimum star-sum score.
- (iii) Merge the  $(k - 1)$  constrained pair-wise sequence alignments between  $S_c$  and other  $S_j$  under the positions  $(r_1, \dots, r_\alpha)$  into a constrained alignment matrix. We elaborate on Steps (i) to (iii) of the above algorithm in the discussion below.

(i) *Aligning a candidate center sequence with another sequence under a list of constrained positions*  $(r_1, \dots, r_\alpha)$  — WLOG, assume that the candidate center sequence is  $S_1$ . Given  $r_1, r_2, \dots, r_\alpha$ , we perform the CPSA algorithm on  $S_1$  with  $S_2 \dots S_k$  under  $(r_1, r_2, \dots, r_\alpha)$ , using a slightly modified recurrence in Theorem 1, treating  $S_c$  as  $S_1$  and  $S_p$  as  $S_2$  ( $2 \leq p \leq k$ ). Below,  $D(i, j, \gamma)$  denotes the optimal constrained pair-wise sequence alignment score of sequences  $S_1[1..i]$  and  $S_2[1..j]$  with constrained characters  $P[1..\gamma]$  matched in positions  $r_1, \dots, r_\gamma$ , respectively.

$$D(i, j, \gamma) = \min \begin{cases} D(i-1, j-1, \gamma-1) + \delta(S_1[i], S_2[j]) \\ \quad \text{if } r_\gamma = i, S_1[i] = S_2[j] = P[\gamma], \\ D(i-1, j-1, \gamma) + \delta(S_1[i], S_2[j]) & \text{if } i, j > 0, \\ D(i-1, j, \gamma) + \delta(S_1[i], -) & \text{if } i > 0, \\ D(i, j-1, \gamma) + \delta(-, S_2[j]) & \text{if } j > 0, \end{cases} \quad (1)$$

with boundary conditions  $D(0, 0, 0) = 0$ ,  $D(i, 0, \gamma) = \infty$  for  $\gamma \geq 1$ ,  $0 \leq i \leq n_1$ , and  $D(0, j, \gamma) = \infty$  for  $\gamma \geq 1$ ,  $0 \leq j \leq n_2$ .

Suppose  $n_1 = |S_1|$  and  $n_2 = |S_2|$ . Notice that using the above recurrence, for any  $1 \leq \gamma \leq \alpha$ , the computation path from  $D(n_1, n_2, \alpha)$  to  $D(0, 0, 0)$  must pass through some points  $D(r_\gamma, j, \gamma)$  with  $1 \leq j \leq n_2$ . This implies that the alignment occurs in  $S_1$  at the positions  $(r_1, r_2, \dots, r_\alpha)$ .

(ii) *Finding the optimal center sequence and the constrained positions* — Consider each sequence  $S_i$  and a list of positions of occurrence  $(r_1, r_2, \dots, r_\alpha)$  of  $P$  in  $S_i$  where  $1 \leq i \leq k$ . The combination  $(S_i; r_1, r_2, \dots, r_\alpha)$  that gives the minimum sum of constrained pair-wise alignment scores with other sequences under the positions  $(r_1, r_2, \dots, r_\alpha)$  is selected as the center sequence  $S_c$  and the list of positions to be aligned with  $P$ .

(iii) *Merging the  $(k - 1)$  constrained pair-wise alignments* — Based on the optimal center sequence, we construct a CMSA, denoted by  $A$ . Suppose the center

sequence of  $S$  is  $S_1$  under a list of positions  $(r_1, r_2, \dots, r_\alpha)$ . There are  $(k-1)$  constrained pair-wise alignments, one for  $S_1$  aligning with each  $S_j$ , for  $2 \leq j \leq k$ . Suppose  $|S_1| = n$ , and let  $A_j$  be the optimal constrained pair-wise alignment of  $S_1$  and  $S_j$  under  $(r_1, r_2, \dots, r_\alpha)$ . Define  $s_0$  and  $s_n$  be the longest sequences of spaces inserted before  $S_1[1]$  and after  $S_1[n]$  in all  $(k-1)$   $A_j$ 's, respectively. Similarly for  $1 \leq i \leq n-1$ , let  $s_i$  be the longest sequence of spaces between  $S_1[i]$  and  $S_1[i+1]$  in all  $(k-1)$   $A_j$ 's. Initially, set  $A$  to contain a single row  $S'_1 = [s_0 \oplus S_1[1] \oplus s_1 \oplus S_1[2] \oplus \dots \oplus s_{i-1} \oplus S_1[i] \oplus s_i \oplus \dots \oplus S_1[n] \oplus s_n]$ , where the  $\oplus$  operator denotes the string concatenation operation. Note that  $|S'_1| = |S_1| + \sum_{0 \leq i \leq n} |s_i|$ .

For each  $S_j$  with  $2 \leq j \leq k$ , add  $S_j$  to  $A$  according to the optimal constrained pair-wise sequence alignment  $(\frac{\tilde{S}_1}{\tilde{S}_j})$  of  $S_1$  and  $S_j$ , i.e., insert columns of spaces to  $(\frac{\tilde{S}_1}{\tilde{S}_j})$  until  $\tilde{S}_1$  is identical to  $S'_1$ .

Notice that the insertion of spaces during the construction of  $A$  does not change the pair-wise alignment score of  $S_1$  with each of the other sequences with respect to  $P$  under the positions  $(r_1, r_2, \dots, r_\alpha)$ . Therefore,  $A$  is the constrained multiple sequence alignment for  $S = \{S_1, \dots, S_k\}$  and  $P$  with the minimum star-sum score.

## 5.2. Complexities of the center-star algorithm for CMSA

Based on the recurrence equation presented in Equation 1, the optimal constrained pair-wise alignment of  $S_1$  with  $S_2$ , under a set of  $\alpha$  positions  $\{r_1, \dots, r_\alpha\}$  matching  $P$  takes time and space  $O(\alpha n^2)$ . This can be further reduced to  $O(n^2)$  time and space.

**Lemma 1.** *Consider two sequences  $S_1$  and  $S_2$ , and a constrained sequence  $P$  with  $|S_1| = n_1$ ,  $|S_2| = n_2$  and  $|P| = \alpha$ . Given a list of positions  $r = (r_1, \dots, r_\alpha)$  such that  $S_1[r_\gamma]$  is to match  $P[\gamma]$ , for all  $1 \leq \gamma \leq \alpha$ , it suffices to compute only  $O(n_1 n_2)$  entries in the matrix  $D(i, j, \gamma)$  to obtain  $D(n_1, n_2, \alpha)$ .*

**Proof.** Based on Equation 1, we have the following three observations about the computation of  $D(i, j, \gamma)$ . Consider any  $0 \leq \gamma \leq \alpha$ , and any  $1 \leq j \leq n_2$ . (i) When  $i < r_\gamma$ ,  $D(i, j, \gamma) = \infty$ . (ii) When  $i = r_\gamma$ ,  $D(i, j, \gamma)$  is computed from  $D(i-1, j-1, \gamma-1)$ . (iii) When  $i > r_\gamma$ ,  $D(i, j, \gamma)$  is computed from  $D(i', j', \gamma)$  for some  $i' \leq i$  and  $j' \leq j$ . As a result, we can see that for any  $0 \leq \gamma \leq \alpha$ , we only need to compute the entries  $D(i, j, \gamma)$  for all  $r_\gamma \leq i \leq r_{\gamma+1} - 1$  and all  $1 \leq j \leq n_2$ . (We set  $r_0 = 0$  and  $r_{\alpha+1} = n_1 + 1$  for the boundary case.) Therefore, the total number of entries that we need to compute equals to  $\sum_{0 \leq \gamma \leq \alpha+1} (r_{\gamma+1} - r_\gamma) n_2 = O(n_1 n_2)$ .  $\square$

Based on Lemma 1, we can compute the optimal constrained alignment for  $S_1$  and  $S_2$  with  $P$  matched in a particular sequence of positions as shown in Algorithm 2. In Step (i), we need to compute  $(k-1)$  pair-wise alignments for each combination  $(S; r_1, \dots, r_\alpha)$  and there are  $C$  such combinations. Therefore, by Lemma 1, Step (i) can be computed in  $O(Ckn^2)$  time. To find the best combination, we only need to keep track of the current best one as we consider a new combination. Therefore, Steps (i) and (ii) together takes  $O(Ckn^2)$  time and  $O(n^2)$  space. For Step (iii),

**Algorithm 2:** The dynamic programming of Center-star alignment (Step (i))

---

```

begin
  // Initialization:
  Initialize  $D(0, 0, 0)$ ,  $D(i, 0, \gamma)$ , and  $D(0, j, \gamma)$ , for  $0 \leq i \leq n_1$ ,  $0 \leq j \leq n_2$ ,
  and  $1 \leq \gamma \leq \alpha$ , according to Equation 1.
  // Dynamic Programming: set  $r_0 = 0, r_{\alpha+1} = n_1$ 
  for  $\gamma = 0$  to  $\alpha$  do
    for  $i = r_\gamma$  to  $r_{\gamma+1}$  do
      for  $j = 0$  to  $n_2$  do
        If  $D(i, j, \gamma)$  is not initialized, compute  $D(i, j, \gamma)$  according to
        Equation 1 in terms of  $D(i-1, j-1, \gamma-1)$ ,  $D(i-1, j-1, \gamma)$ ,
         $D(i-1, j, \gamma)$  and  $D(i, j-1, \gamma)$ .
  end

```

---

notice that the resulting sequence  $S'_1$  has length at most  $kn$ . If we store the whole resulting alignment matrix, we need  $O(k^2n)$  space and the merging would take  $O(k^2n)$  time. However, we can simply store the locations of the non-space characters of the sequences in the alignment matrix. Then the merging can be done incrementally by adding each sequence in turn using  $O(n)$  time, i.e., in total the merging takes  $O(kn)$  time. The space requirement can also be reduced to  $O(kn)$ . As a result, the overall time and space complexities of the center-star algorithm is  $O(Ckn^2)$  and  $O(n^2)$ , respectively.

### 5.3. Performance of the center-star algorithm for CMSA

The following theorem shows that the center-star approximation algorithm for CMSA has an approximation ratio  $(2 - \frac{2}{k})$ . Define the distance  $\Delta(S'_i, S'_j)$  of two aligned sequences  $S'_i$  and  $S'_j$  as the sum of pair-wise distances between the two characters at the same positions in  $S'_i$  and  $S'_j$ , i.e.,  $\Delta(S'_i, S'_j) = \sum_{1 \leq p \leq |S'_i|} \delta(S'_i[p], S'_j[p])$ .

**Theorem 3.** *Given  $S = \{S_1, \dots, S_k\}$  and a constrained sequence  $P$ . Suppose  $A^s$  is the alignment output by the constrained center-star algorithm, and  $A^*$  be the optimal constrained alignment with respect to  $P$ . Then,  $\frac{sp\_score(A^s)}{sp\_score(A^*)} \leq 2 - \frac{2}{k}$ .*

**Proof.** For any alignment matrix  $A$ , let  $A_i$  be the  $i$ -th row of  $A$ , for  $1 \leq i \leq k$ , and  $ss\_score_i(A)$  be the star-sum score of  $A$  with  $A_i$  as the center sequence. Let  $A_c$  be the optimal center sequence of  $A$ . Since  $A^*$  is a CMSA for  $S$  and  $P$ ,  $sp\_score(A^*) = \sum_{1 \leq i < j \leq k} \Delta(A_i^*, A_j^*)$ . Then,

$$\begin{aligned}
 sp\_score(A^*) &= \frac{1}{2} \sum_{1 \leq i, j \leq k, i \neq j} \Delta(A_i^*, A_j^*) \\
 &= \frac{1}{2} \sum_{1 \leq i \leq k} \left( \sum_{1 \leq j \leq k, i \neq j} \Delta(A_i^*, A_j^*) \right) \\
 &= \frac{1}{2} \sum_{1 \leq i \leq k} (ss\_score_i(A^*)) \\
 &\geq \frac{k}{2} \min_{1 \leq i \leq k} (ss\_score_i(A^*)) \\
 &\geq \frac{k}{2} (ss\_score_c(A^s)).
 \end{aligned}$$

On the other hand,

	Data Set 0	Data Set 1	Data Set 2	Data Set 3

Table 3. Sequences used in data sets 0 to 3

$$\begin{aligned}
sp\_score(A^s) &= \frac{1}{2} \sum_{1 \leq i, j \leq k, i \neq j} \Delta(A_i^s, A_j^s) \\
&\leq \frac{1}{2} \sum_{1 \leq i, j \leq k, i \neq j, i \neq c, j \neq c} (\Delta(A_i^s, A_c^s) + \Delta(A_c^s, A_j^s)) \\
&\quad + \frac{1}{2} (\sum_{1 \leq j \leq k, j \neq c} \Delta(A_c^s, A_j^s) + \sum_{1 \leq i \leq k, i \neq c} \Delta(A_i^s, A_c^s)) \\
&= \frac{2(k-1)}{2} \sum_{1 \leq i \leq k, i \neq c} \Delta(A_i^s, A_c^s) \\
&= (k-1)(ss\_score_c(A^s)).
\end{aligned}$$

Note that the inequality above (i.e., lines 1 and 2) is due to the triangle inequality. Therefore,  $\frac{sp\_score(A^s)}{sp\_score(A^*)} \leq \frac{2(k-1)}{k} = 2 - \frac{2}{k}$ , and the theorem follows.  $\square$

## 6. Empirical Results

In Section 6.1, we evaluate the performance of our CPSA and CMSA algorithms using four data sets of RNase sequences taken from the NCBI<sup>b</sup>. In Section 6.2, we show that, in practice,  $C$ , the total number of occurrences of the constrained sequence as a subsequence in all sequences, is much smaller than  $n^2$ .

### 6.1. Experiments on CPSA and CMSA algorithms

All our experiments are conducted on an Intel workstation with 2.0 GHz CPU and 4GB main memory. First, we use CPSA to align two RNase sequences (with lengths about 150) with three constrained characters ( $\alpha = 3$ ), using our CPSA algorithm (Section 3) and Tang *et al.*'s constrained pair-wise sequence algorithm<sup>15</sup>. Tang *et al.*'s CPSA algorithm took 127 seconds and 400 MB memory. For the same problem instance, our CPSA algorithm ran within a fraction of second with only 1.5 MB of memory space. This shows the practicality of our CPSA algorithm especially for long sequences and long constrained sequence.

To evaluate the performance of different CMSA algorithms, we implemented the original Tang *et al.*'s progressive CMSA algorithm<sup>15</sup>, the improved progressive CMSA algorithm, and the constrained center-star algorithm. We ran these CMSA algorithms on four sets of RNase sequences, summarized in Table 3. In data set 0, we

Data set 2	63315	31776
Data set 3	62966	59021

Table 5. Alignment scores of the two algorithms after the refinement by ClustalW

used the same set of 7 RNase sequences used by Tang *et al.*<sup>15</sup> We obtained 3 other data sets of RNase sequences from the NCBI; data sets 1 and 2 contain 6 RNase sequences of lengths about 180, and data set 3 contains 5 long RNase sequences (with maximum length 327). Since we cast the CMSA as a minimization problem, we used a modified scoring function based on Pam70. These four data sets were aligned using the CMSA algorithms, measuring the running time, memory requirement and the modified minimizing-Pam70 alignment score. These alignments were then post-processed using the web-tool ClustalW<sup>c</sup> as described by Tang *et al.*<sup>15</sup>.

Table 4 summarizes the performance of the three different CMSA algorithms on these data sets; while the performance of the algorithms after the ClustalW refinement on these data sets is presented in Table 5. The alignments of data sets 0 to 3, using the constrained center-star algorithm, are shown in Figure 1. Due to the page limit, the alignment matrices are divided into blocks of 90 characters, the first 90 characters of each sequence are listed first before the subsequent blocks. Columns that match the constrained characters are marked by an asterisk (\*).

Comparing the alignment matrices produced by center-star approximation algorithm and Tang *et al.*'s progressive CMSA algorithm<sup>15</sup> in data sets 1, 2 and 3, we note that the constrained characters  $P[1]..P[\alpha]$  are aligned at different columns of the alignment matrices. Computationally, the center-star approximation algorithm for CMSA produces alignments with better SP alignment scores (see Table 4).

## 6.2. Number of constraint Occurrences

We refer to the paper by Tang *et al.*<sup>15</sup> for an application used for CMSA. In their experiments, seven RNase sequences were aligned so that the three active-site residues, "HKH", were in the same columns in the alignment matrix. This motivates the CMSA problem as all RNase sequences contain the active-site residues "HKH" that are essential for the main functionality of the RNase degrading to RNA. In

<sup>c</sup>The ClustalW web tool is provided by *European Bioinformatics Institute*, URL: <http://www.ebi.ac.uk/clustalw/>.

No. of samples	1954	2351
Percentage	83.11%	100.0 %
Max sequence length	500	3989
Median Occurrences	42	56
Average Occurrences	105	464
80 Percentile	124	413
90 Percentile	241	1248

Table 6. Occurrences of constraint “HKH” in RNase sequences from NCBI

our experiment, we show that  $C$ , the total number of occurrences of the constraint “HKH” in each sequence is reasonably small. Since the value of  $C$  is relatively small, the running time of our center-star algorithm is more efficient than the  $O(\alpha kn^4)$ -time algorithm described by Tang *et al.*<sup>15</sup> There are totally 2351 sequences from the NCBI. In these 2351 RNase sequences, a total of 1954 sequences, or 83%, contain less than 500 residues. For each RNase, we measured the mean, mode and average number of occurrences of the constraint “HKH” and the result is reported in Table 6.

CMSA is usually done for a set of sequences of approximately the same length. As shown in Table 6, for CMSA of  $k$  sequences with lengths below 500, we have  $C \leq 105k$  on average and  $C \leq 241k$  for 90% of these RNase sequences. Even among the longer RNase sequences, the average number of occurrences is only about 464. Thus, the running time of our center-star algorithm is  $O((500k)kn^2)$  on average which is much shorter than the running time  $O(\alpha kn^4)$  of Tang *et al.*’s algorithm<sup>15</sup>.

## 7. Conclusion

Using traditional MSA tools, biologists have limited control over the output of the sequence alignment. They can only choose high level alignment parameters such as gap penalty, scoring function, etc. As such, they are unable to incorporate their knowledge about the sequences, such as known functionalities and structures of the input sequences for use by the sequence alignment tool. This information is essential for accurate and biologically meaningful sequence alignment. Constrained sequence alignment provides users with the ability to differentiate important residues that need to be aligned together over other residues. This problem was first studied by Tang *et al.*<sup>15</sup> However, many existing techniques developed for MSA in the literature do not work for the CMSA problem due to the time and space complexities of  $O(\alpha n^4)$ . In this paper, we reduce the time and space complexities of solving the optimal pair-wise constrained alignment from  $O(\alpha n^4)$  to  $O(\alpha n^2)$ . With this improvement, existing techniques for MSA can now be modified to solve the CMSA problem. We have demonstrated how the center-star sequence approximation algorithm can be applied to solve the CMSA problem. With the reduction in time and space complexities, it is hoped that the improved quality of sequence alignment can help biologists. It is worth-mentioning that the constrained center-star alignment problem can be shown to be NP-hard, exploiting approximation algorithms of this problem for the constrained multiple sequence alignment problem would be of theoretic and practical interest.

**Acknowledgement:** We thank the reviewer for pointing out that the space of our pair-wise constrained alignment can be improved to  $O(\alpha n)$ .
